Data preprocessing
Data storage and manipulation

Mobility Scenario

Rationale

Improve user experience of **passengers with special needs** and their **caregivers**

Objective

Analyze user's **context** and react to **changing conditions**

Approach

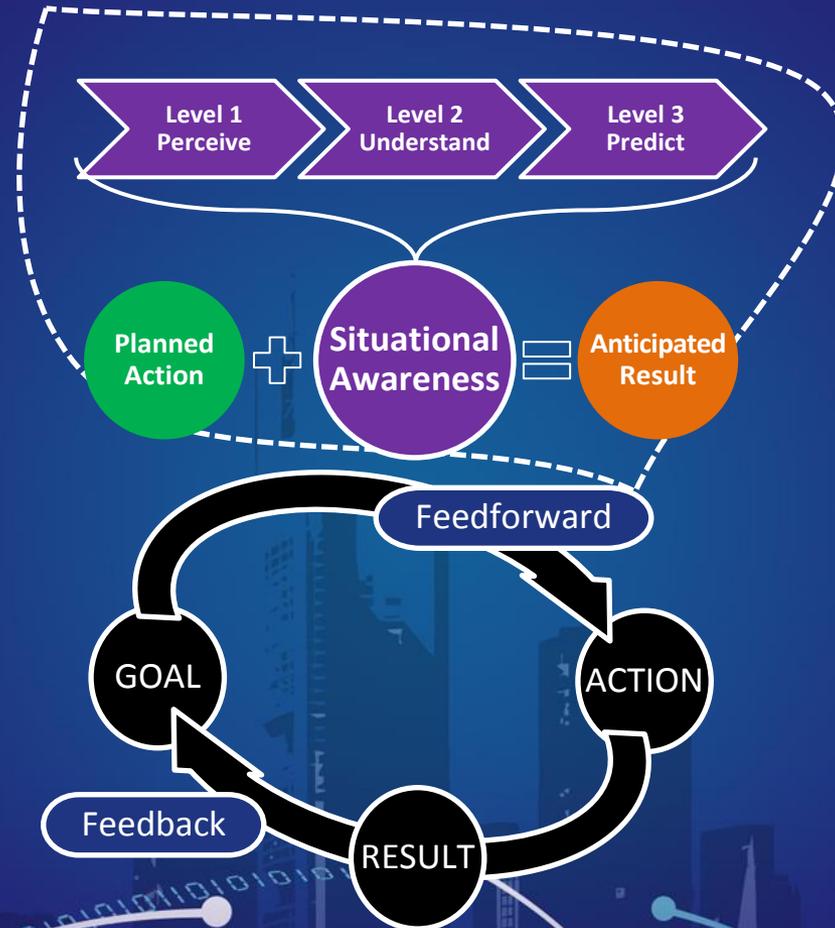

Monitor data from **3600 sensors**
Historical and real-time data analysis

Challenge

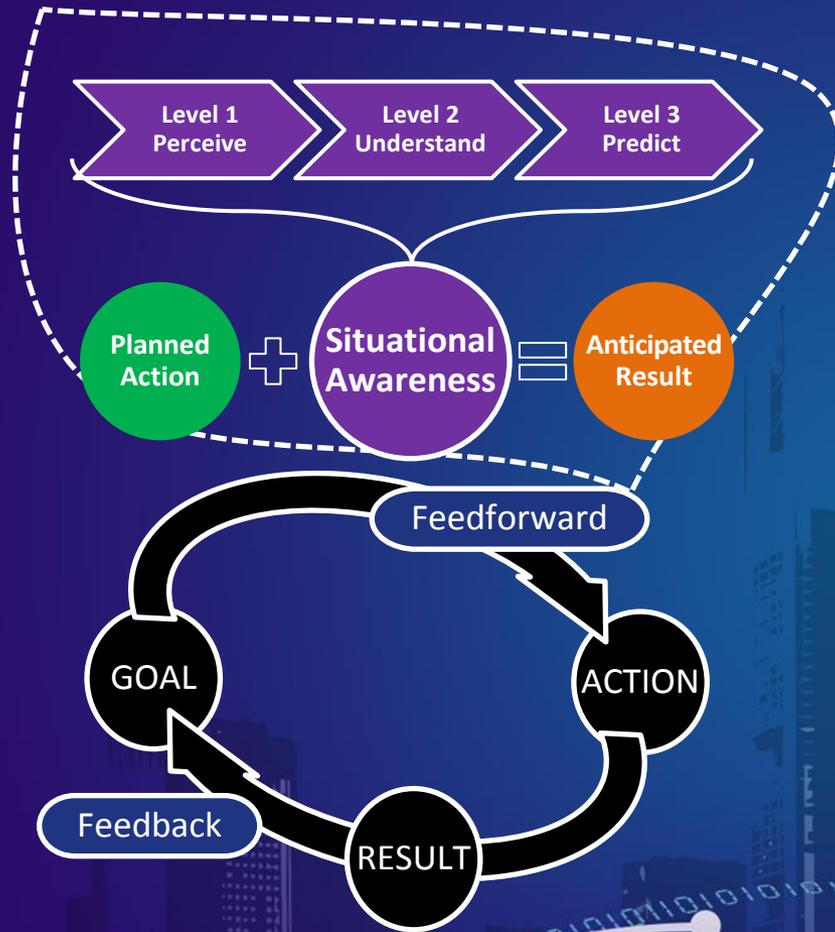

Dynamic Traffic Congestion Prediction:

- **Machine Learning**
- **Complex Event Processing**
- **Cloud Storage**

Situational Awareness

Situational Awareness

L1 - Ingestion

- Collect data for real time response
- Efficient Storage

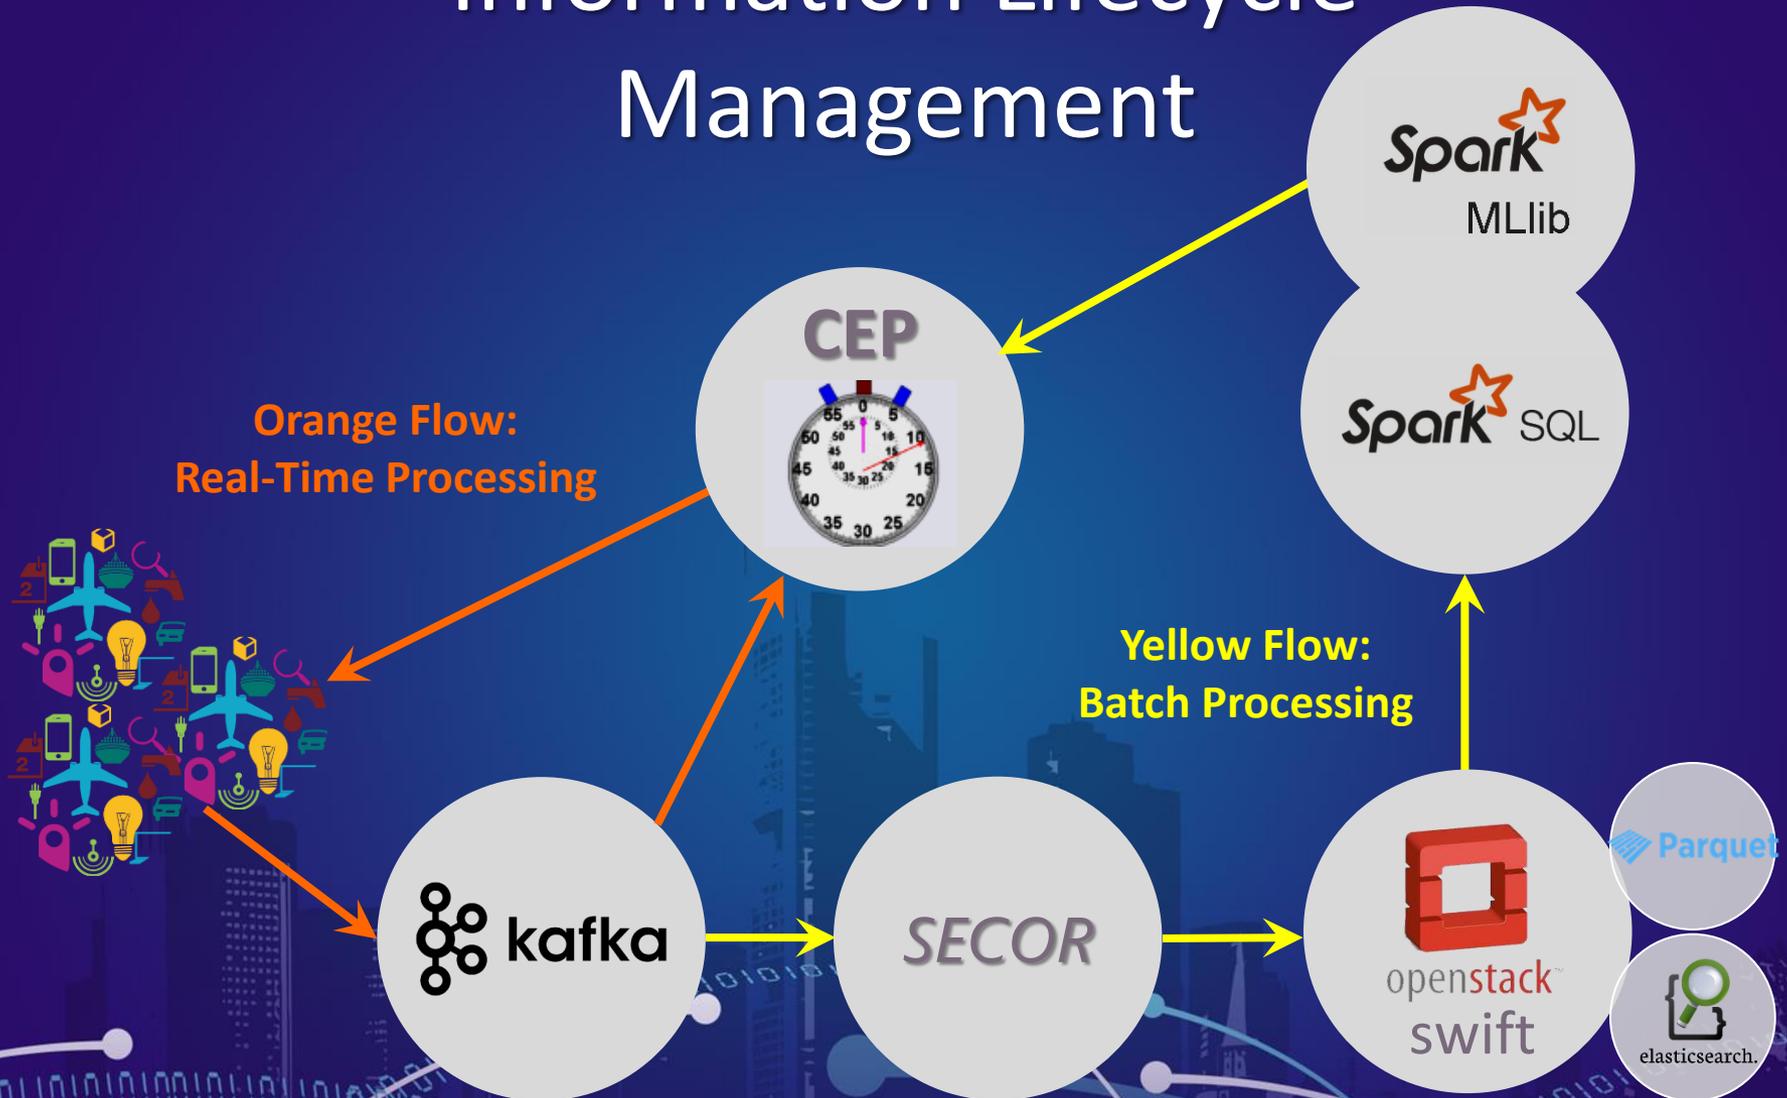

L2 - Analytics

- Historical data Machine Learning
- Efficient data access
- Real-Time CEP

L3 - Projection

- Evolution of current situation

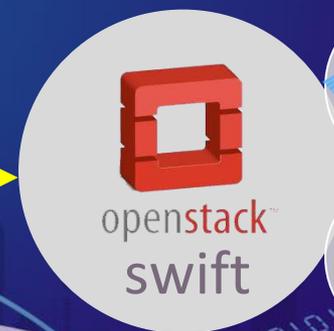

Information Lifecycle Management

Information Lifecycle Management

Ingestion - Collect historical time series data

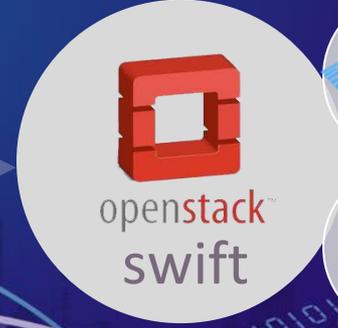

- Collect data from devices
- Aggregate into objects with metadata
- Index the metadata

Information Lifecycle Management

Analytics - Learn patterns in data

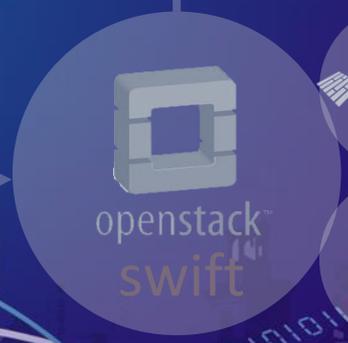

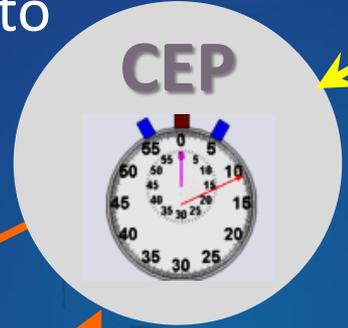

- Based on history
- Access historical data efficiently
- Generate thresholds, classifiers etc.

Information Lifecycle Management

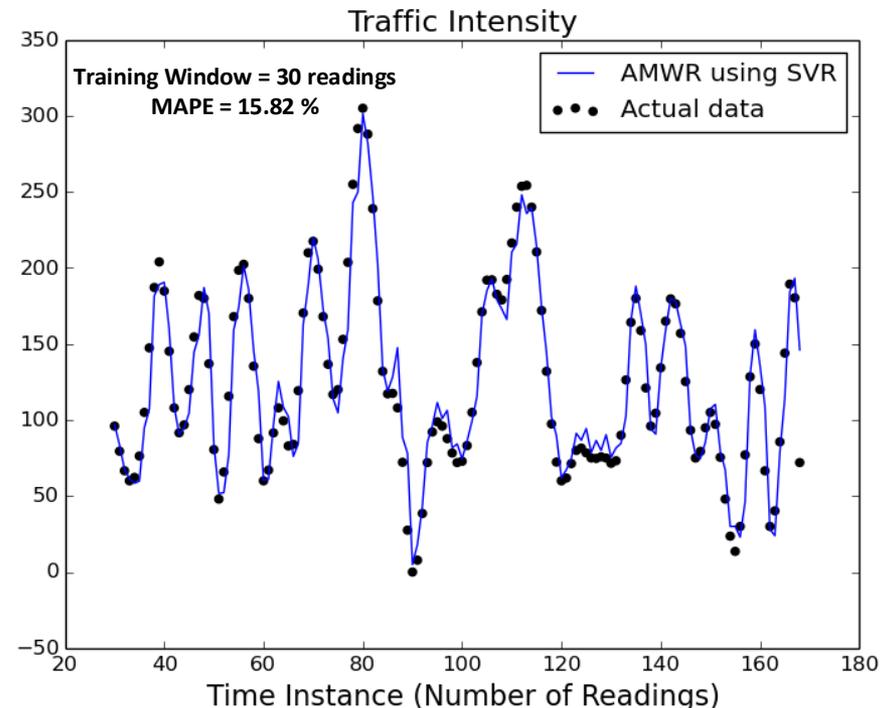

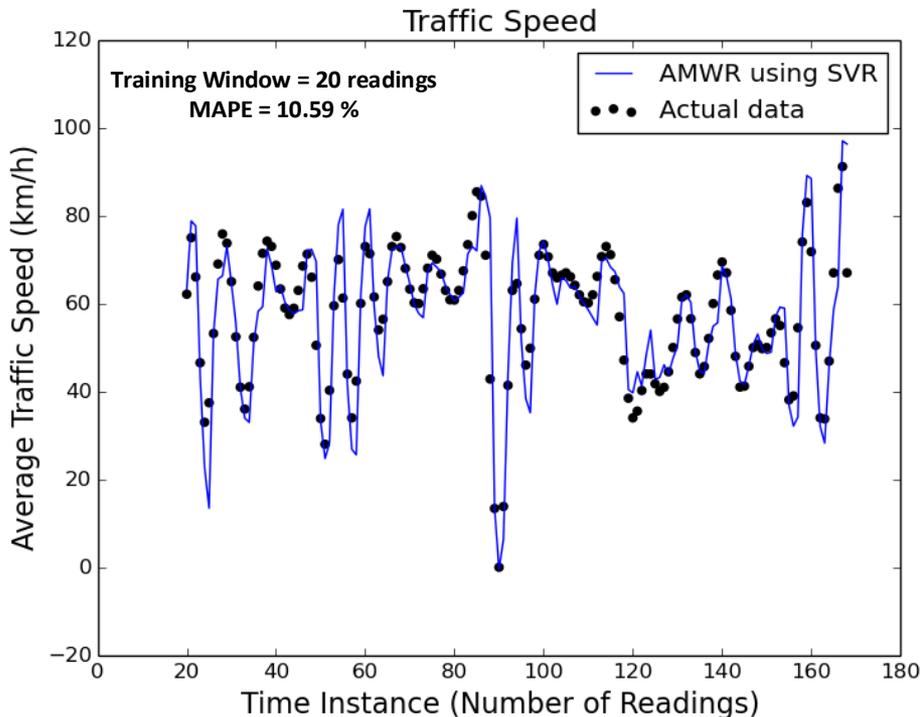

Real-Time Response

- Apply derived knowledge to real time data stream
- Take actions

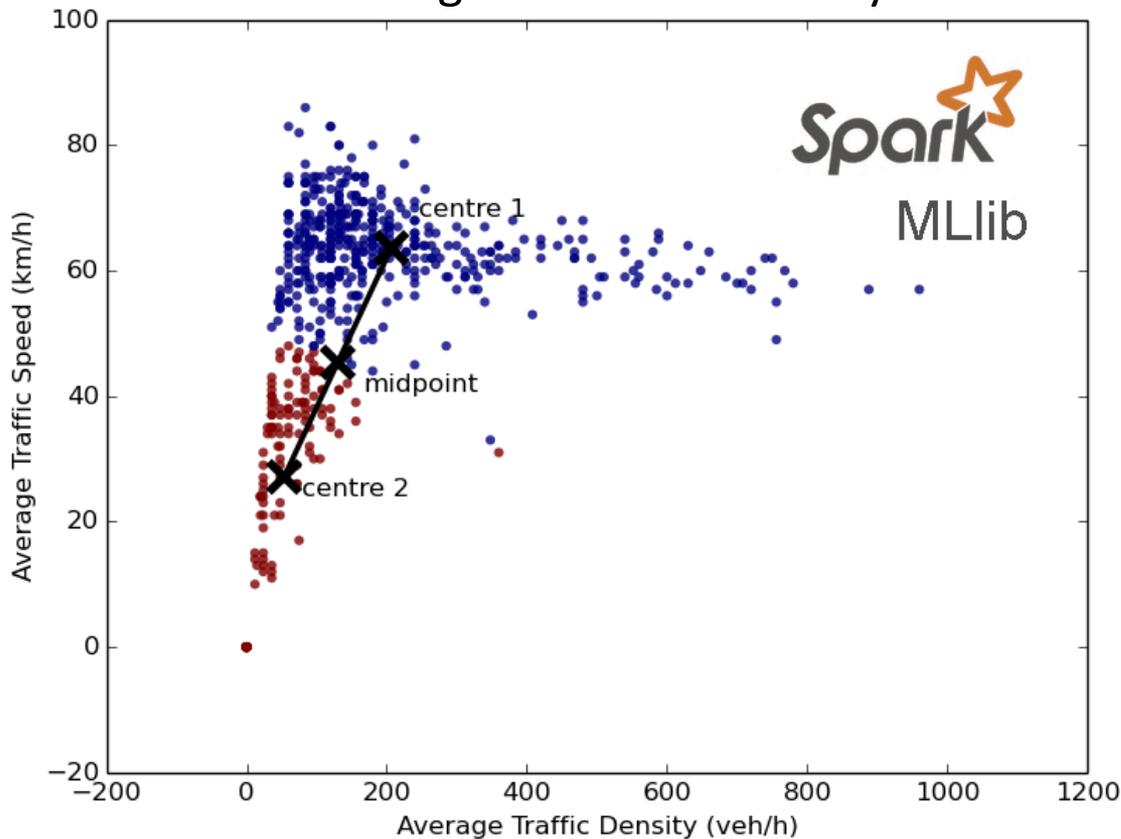

Adaptive Moving Window Regression (AMWR)

- Support multiple Regression methods
 - SVR, ANN, Linear Regression
- Automatically finds optimized training window size during training phase
 - Traffic speed = 20 readings
 - Traffic Intensity = 30 readings
- Model Training and Deployment
- Evaluate the Error and retrain the model as new data arrive
 - If error > 20% → reduce prediction window
 - If error < 5 % → increase prediction window
 - Range = 2-4 samples

K-Means Clustering

Morning Traffic on Weekdays

- Use Spark MLlib k-means clustering to separate data into 2 clusters
- Find the midpoint between the 2 cluster centres
- Use this midpoint to generate the thresholds
- Re-run algorithm when quality of clusters decreases
- Use silhouette index to measure quality
